

## Summary

A pregnant mother of 29 years of age from Rikillagaskada, was referred to Kalubowila STD clinic by a Consultant Obstetrician and Gynaecologist at Colombo South Teaching Hospital for further management of *Trichomonas* infection. By the time, she was at 37 weeks of period of amenorrhoea (POA). Even though the patient has experienced a scanty yellowish vaginal discharge during last two weeks, she has not sought medical advice as she has considered this as a normal phenomena in pregnancy. On examination, offensive greyish vaginal discharge was noted. Furthermore, features of strawberry cervix and a cervical growth at twelve o'clock position were observed. *Trichomonas vaginalis* infection was confirmed as it was detected in her wet vaginal smear and urine full report. She was treated by oral metronidazole 400mg twice-a-day for one-week duration. Her spouse was also found to be having *Trichomonas vaginalis* infection and he was also treated with metronidazole. Since both partners strongly denied any extra marital sexual relationships, further contact tracing was not possible.
